

CS121 Problem Set #6

1a. No dependencies since one value of a doesn't map to one value of b and vice versa

1b.  $b \rightarrow a$  since a can have multiple b values but not vice versa

1c.  $a \rightarrow b$  since same rational as part b

1d.  $a \rightarrow b$  and  $b \rightarrow a$  since each pair is unique

2. Union rule: If  $\alpha \rightarrow \beta$  holds, and  $\alpha \rightarrow \gamma$  holds, then  $\alpha \rightarrow \beta\gamma$  holds.

Given  $\alpha \rightarrow \beta$ ,  $\alpha\alpha \rightarrow \beta\alpha$  by the Augmentation rule

Given  $\alpha \rightarrow \gamma$ ,  $\alpha\beta \rightarrow \gamma\beta$  by the Augmentation rule

Since  $\alpha\alpha \rightarrow \beta\alpha$  and  $\alpha\beta \rightarrow \gamma\beta$ ,  $\alpha\alpha \rightarrow \gamma\beta$  by the Transitivity rule

Thus,  $\alpha \rightarrow \gamma\beta$  since  $\alpha\alpha$  is two identical sets

Decomposition rule: If  $\alpha \rightarrow \beta\gamma$  holds, then  $\alpha \rightarrow \beta$  holds and  $\alpha \rightarrow \gamma$  holds.

Given  $\beta\gamma$ ,  $\beta\gamma \rightarrow \beta$  and  $\beta\gamma \rightarrow \gamma$  by the Reflexivity rule

Given  $\alpha \rightarrow \beta\gamma$  and  $\beta\gamma \rightarrow \beta$ ,  $\alpha \rightarrow \beta$  by the Transitivity rule

Given  $\alpha \rightarrow \beta\gamma$  and  $\beta\gamma \rightarrow \gamma$ ,  $\alpha \rightarrow \gamma$  by the Transitivity rule

Pseudotransitivity rule: If  $\alpha \rightarrow \beta$  holds, and  $\gamma\beta \rightarrow \delta$ , then  $\alpha\gamma \rightarrow \delta$  holds.

Given  $\alpha \rightarrow \beta$ ,  $\alpha\gamma \rightarrow \beta\gamma$  by Augmentation rule

Given  $\alpha\gamma \rightarrow \beta\gamma$  and  $\gamma\beta \rightarrow \delta$ , then  $\alpha\gamma \rightarrow \delta$  by Transitivity rule

3a. Must find candidate keys that are a superkey for R:

NOTE:  $\alpha \rightarrow \alpha$  for any set by Reflexivity

Given  $A \rightarrow BC$ ,  $A \rightarrow B$  and  $A \rightarrow C$  by Decomposition

Since  $B \rightarrow D$  and  $A \rightarrow B$ ,  $A \rightarrow D$  by Transitivity

Given  $A \rightarrow CD$  by Union ( $A \rightarrow C$  and  $A \rightarrow D$ ) and  $CD \rightarrow E$ ,  $A \rightarrow E$  by Transitivity

Thus,  $A \rightarrow ABCDE$  by Union so A is a candidate key

Since  $A \rightarrow ABCDE$  and  $E \rightarrow A$ ,  $E \rightarrow ABCDE$  by Transitivity

So, E is also a candidate key

Since  $CD \rightarrow E$  and  $E \rightarrow ABCDE$ ,  $CD \rightarrow ABCDE$  by Transitivity

CD is a candidate key

Given  $B \rightarrow D$ ,  $BC \rightarrow CD$  by Augmentation

Given  $BC \rightarrow CD$  and  $CD \rightarrow E$ ,  $BC \rightarrow ABCDE$  by Transitivity

BC is a candidate key

Thus, (A, E, BC, CD) are the candidate keys

3b. We can use the candidate keys to find all dependencies:

$A \rightarrow ABCDE$  and all dependencies generated from this by applying the Decomposition rule

$E \rightarrow ABCDE$  and all dependencies generated from this by applying the Decomposition rule

$BC \rightarrow ABCDE$  and all dependencies generated from this by applying the Decomposition rule

$CD \rightarrow ABCDE$  and all dependencies generated from this by applying the Decomposition rule

Adding to this, we can create a ton of function dependencies by putting a candidate key and any set of attributes from R on the left and any subset of R on the right. Since the candidate key being paired with other sets in R will create a ton of other dependencies.

Then, we must consider the last restriction in F:

$B \rightarrow D$

$B \rightarrow BD$  by Augmentation and Union

$B \rightarrow B$  by Decomposition

$BD \rightarrow BD$  by Augmentation of  $B \rightarrow B$

$BD \rightarrow B$  and  $BD \rightarrow D$  by Decomposition

Lastly, we need the remaining trivial dependencies:

$C \rightarrow C$  and  $D \rightarrow D$  by Reflexivity

All the mentioned dependencies make up  $F^+$ .

4. Given  $R(A, B, C, D)$ , does  $A \rightarrow\rightarrow BC$  logically imply  $A \rightarrow\rightarrow B$  and  $A \rightarrow\rightarrow C$ ?

No, given  $A \rightarrow\rightarrow BC$ , only  $A \rightarrow\rightarrow B$  or  $A \rightarrow\rightarrow C$  can be satisfied, not both. Take for example this table:

A	B	C	D
1	1	1	3
1	1	2	4
1	1	1	4
1	1	2	3

This satisfies  $A \rightarrow\rightarrow BC$  since  $t1[A] = t2[A] = t3[A] = t4[A]$ ,  $t1[BC] = t3[BC]$  and  $t2[BC] = t4[BC]$ ,  $t1[R - BC] = t4[R - BC]$  and  $t2[R - BC] = t3[R - BC]$  (by definition). We can also infer by that definition that  $A \rightarrow\rightarrow C$  by the same definition. However, we see that this does not hold for  $A \rightarrow\rightarrow B$  since the last part of the definition does not hold ( $t1[R - B] = t4[R - B]$  and  $t2[R - B] = t3[R - B]$ ). If we create a similar table having all the C values equal (e.g. flip the B and C columns above), we get  $A \rightarrow\rightarrow B$  but not  $A \rightarrow\rightarrow C$ .

5a.  $F = \{ A \rightarrow E, BC \rightarrow D, C \rightarrow A, AB \rightarrow D, D \rightarrow G, BC \rightarrow E, D \rightarrow E, BC \rightarrow A \}$

$BC \rightarrow D$  is extraneous in  $F$  since  $C \rightarrow A$  becomes  $BC \rightarrow AB$  by Augmentation

And  $BC \rightarrow AB$  with  $AB \rightarrow D$  becomes  $BC \rightarrow D$  by Transitivity

$\{A \rightarrow E, C \rightarrow A, AB \rightarrow D, D \rightarrow G, BC \rightarrow E, D \rightarrow E, BC \rightarrow A\}$

Union rule on  $D \rightarrow E$  and  $D \rightarrow G$

$\{A \rightarrow E, C \rightarrow A, AB \rightarrow D, D \rightarrow EG, BC \rightarrow E, BC \rightarrow A\}$

$BC \rightarrow E$  is extraneous in  $F$  since  $BC \rightarrow A$  and  $A \rightarrow E$  by Transitivity

$\{A \rightarrow E, C \rightarrow A, AB \rightarrow D, D \rightarrow EG, BC \rightarrow A\}$

$B$  is extraneous in  $BC \rightarrow A$  since  $C \rightarrow A$  and join duplicates of  $C \rightarrow A$

$F_c = \{ A \rightarrow E, C \rightarrow A, AB \rightarrow D, D \rightarrow EG \}$

5b. Compute  $BC^+$  since BC is common

$BC^+ = BC$  and  $BC \rightarrow D, BC \rightarrow E, BC \rightarrow A$

$BC^+ = ABCDE$  and  $D \rightarrow G$

$BC^+ = ABCDEG$  so BC is a superkey

Next, find  $B^+$  and  $C^+$ :

$B^+ = B$  and there's nothing else we can do

$C^+ = C$  and  $C \rightarrow A$

$C^+ = CA$  and  $A \rightarrow E$

$C^+ = CAE$  and that is it

Since attribute-set closure of all subsets is not R, BC is a candidate key.

5c. We consider each dependency in F:  $A \rightarrow E, C \rightarrow A, D \rightarrow E, D \rightarrow G, AB \rightarrow D$  are not in BCNF while  $BC \rightarrow D, BC \rightarrow E, BC \rightarrow A$  are in BCNF since BC is a candidate key.

Take out  $A \rightarrow E$  first:

$R_1 = (A, E)$  where A is primary key of  $R_1$  so in BCNF

$R_2 = (A, B, C, D, G)$  take out  $D \rightarrow G$

$R_2 = (D, G)$  where D is primary key of  $R_2$  so in BCNF

$R_3 = (A, B, C, D)$  take out  $C \rightarrow A$

$R_3 = (C, A)$  where C is primary key of  $R_3$  so in BCNF

$R_4 = (B, C, D)$  which is in BCNF because BC is candidate key

So, final answer:

$R_1 = (A, E)$  where A is primary key of  $R_1$  ( $A \rightarrow E$ )

$R_2 = (D, G)$  where D is primary key of  $R_2$  ( $D \rightarrow G$ )

$R_3 = (C, A)$  where C is primary key of  $R_3$  ( $C \rightarrow A$ )

$R_4 = (B, C, D)$  since BC is candidate key ( $BC \rightarrow D$  is valid)

Dependencies lost:  $AB \rightarrow D, D \rightarrow E$

5d. Pick  $D \rightarrow EG$  first:

$R_1 = (D, E, G)$  where  $D$  is primary key of  $R_1$  so in BCNF

$R_2 = (A, B, C, D)$  take out  $C \rightarrow A$

$R_2 = (C, A)$  where  $C$  is the primary key of  $R_2$  so in BCNF

$R_3 = (C, B, D)$  and  $BC$  is candidate key of  $R$  given  $F$  so in BCNF

So, final answer:

$R_1 = (D, E, G)$  where  $D$  is primary key of  $R_1$  ( $D \rightarrow EG$ )

$R_2 = (C, A)$  where  $C$  is the primary key of  $R_2$  ( $C \rightarrow A$ )

$R_3 = (C, B, D)$  where  $BC$  is candidate key ( $BC \rightarrow D$  is valid)

Lost Dependencies:  $A \rightarrow E$  and  $AB \rightarrow D$

5e. Using  $F_C$  and adding a candidate key since rest do not have one:

$R_1(A, E)$  where  $A$  is the primary key of  $R_1$  ( $A \rightarrow E$ )

$R_2(C, A)$  where  $C$  is the primary key of  $R_2$  ( $C \rightarrow A$ )

$R_3(D, E, G)$  where  $D$  is the primary key of  $R_3$  ( $D \rightarrow EG$ )

$R_4(A, B, D)$  where  $AB$  is the primary key of  $R_4$  ( $AB \rightarrow D$ )

$R_5(B, C)$  where  $BC$  is a candidate key

6. Let  $R\{\text{course\_id, section\_id, dept, units, course\_level, instructor\_id, term, year, meet\_time, room, num\_students}\} = R\{A, B, C, D, E, G, H, I, J, K, L\}$

6a. Given  $F = \{A \rightarrow CDE, ABHI \rightarrow JKLG, KJHI \rightarrow GAB\}$

Take  $\{KJHI\}^+ = KJHI$  and  $KJHI \rightarrow GAB$  so  $\{KJHI\}^+ = KJHIGAB$

$A \rightarrow CDE$  so  $\{KJHI\}^+ = KJHICDEGAB$

$ABHI \rightarrow JKLG$  so  $\{KJHI\}^+ = ABCDEGHIJKL$

$KJHI$  is a candidate key

$\{ABHI\}^+ = ABHI$  and  $ABHI \rightarrow JKLG$

$\{ABHI\}^+ = ABHIJKLG$  and  $A \rightarrow CDE$

$\{ABHI\}^+ = ABHIJKLGCDE = ABCDEGHIJKL$

ABHI is a candidate key

Thus, { course\_id, section\_id, term, year } and { room, meet\_time, term, year } are candidate keys

6b. Looking at the last two dependencies, we can see that the G on the right hand side is extraneous. Thus, our two canonical covers are (only difference is instructor\_id on right side of second and third dependencies):

{course\_id  $\rightarrow$  dept, units, course\_level; course\_id, section\_id, term, year  $\rightarrow$  meet\_time, room, num\_students; room, meet\_time, term, year  $\rightarrow$  instructor\_id, course\_id, section\_id }

And

{course\_id  $\rightarrow$  dept, units, course\_level; course\_id, section\_id, term, year  $\rightarrow$  meet\_time, room, num\_students, instructor\_id; room, meet\_time, term, year  $\rightarrow$  course\_id, section\_id }

It would make more sense to have instructor\_id in the second dependency. The second dependency gives information about a course at a time, which makes sense to have the instructor\_id in. The last dependency describes a location and time for a class and section, which does not need the instructor\_id.

6c. BCNF decomposition: We have  $F_c = \{ A \rightarrow CDE, ABHI \rightarrow JKL, KJHI \rightarrow AB \}$

Start with (A, B, C, D, E, G, H, I, J, K, L) and take out  $A \rightarrow CDE$

$R_1(A, C, D, E)$  where A is primary key of  $R_1$

(A, B, G, H, I, J, K, L) take out  $ABHI \rightarrow JKL$  and  $KJHI \rightarrow AB$

$R_2(A, B, H, I, J, K, L, G)$  where ABHI is candidate key and KJHI is a candidate key

3NF: Using  $F_c$  and adding candidate keys:

$R_1(A, C, D, E)$  where A is primary key of  $R_1$

$R_2(A, B, H, I, J, K, L, G)$  where ABHI is candidate key and KJHI is a candidate key

These are the same thing. Thus, we must look at the perks of each given the size. Since this is a relatively small database, we do not have to worry about runtime. Thus, we care about the correct and complete representation in the database. For this reason, the 3NF version would be better.

7. Let  $\text{emails}(\text{email\_id}, \text{send\_date}, \text{from\_addr}, \text{to\_addr}, \text{subject}, \text{email\_body}, \text{attachment\_name}, \text{attachment\_body}) = \text{emails}(A, B, C, D, E, G, H, I)$ :

We have  $A \rightarrow BCEG$ ,  $AH \rightarrow I$ , and  $A \twoheadrightarrow D$

NOTE: if  $X \rightarrow Y$  then  $X \twoheadrightarrow Y$

Start with R: (A, B, C, D, E, G, H, I) take out  $A \rightarrow BCEG$ :

(A, B, C, E, G) where A is the primary key

(A, D, H, I) take out  $A \twoheadrightarrow D$

(A, D) where AD is the primary key

(A, H, I) where AH is the primary key

Final:

$\text{sent\_email}(\text{email\_id}, \text{send\_date}, \text{from\_addr}, \text{subject}, \text{email\_body})$  where  $\text{email\_id}$  is primary key

$\text{send\_to}(\text{email\_id}, \text{to\_addr})$  where  $\text{email\_id}$ ,  $\text{to\_addr}$  is primary key of relation and  $\text{email\_id}$  foreign key to  $\text{sent\_email}$

$\text{add\_attachment}(\text{email\_id}, \text{attachment\_name}, \text{attachment\_body})$  where  $\text{email\_id}$ ,  $\text{add\_attachment}$  is primary and  $\text{email\_id}$  is foreign key to  $\text{sent\_email}$

$\text{sent\_email}$  is in 4NF because  $\text{email\_id}$  is a superkey for  $\text{sent\_email}$  which sprouts from the first dependency listed.

$\text{send\_to}$  is in 4NF because both are primary keys which makes a trivial multivalued dependency which sprouts from the second dependency listed.

$\text{add\_attachment}$  is in 4NF because  $\text{email\_id}$  is a superkey for  $\text{add\_attachment}$  which sprouts from the last dependency.
